

Funnel Automation Blueprint

A practical guide to automation of funnels and downloadable funnel systems.

This PDF is delivered only after backend payment capture confirms a paid order.

1. Stack Used

Frontend: static HTML, CSS, and JavaScript for fast pages and clean editing.

Backend: Python HTTP server for lead capture, order creation, order capture, and tokenized delivery.

Payments: PayPal checkout with server-side verification.

Fulfillment: protected file download after order status is paid.

2. Protocol

Step 1: clarify the promise on the lander.

Step 2: move the visitor into checkout with a single next action.

Step 3: collect email and name before payment approval.

Step 4: create the PayPal order on the server.

Step 5: capture the PayPal order on approval.

Step 6: issue download access only after paid confirmation.

3. SOP

Pre-launch checklist:

- Test headline, CTA, and checkout routing.
- Verify lead capture writes to storage.
- Create and capture a sandbox payment.
- Confirm thank-you redirect and token generation.
- Confirm PDF download is blocked before payment and available after payment.

4. Operating Notes

Keep the funnel narrow. One promise, one offer, one CTA path.

Do not send buyers to an unverified file URL.

Store local records for leads and orders so support is traceable.

Switch to live PayPal credentials only after repeated sandbox checks.

5. Delivery Model

Paid order -> local paid status -> tokenized thank-you page -> file download.

That sequence is the control point that keeps the asset gated correctly.

End of blueprint.
